

I have flashed the OS onto the jetson and got it running.

I was also doing research on the jetson figuring out the criteria for our project since it does have 8GB of RAM this would limit the scale of the AI model we can implement along with the other components involved within our project. For example if we were to use a 1080p camera this would likely require more system resources and would be fighting over them with the AI model. Then I realised the Jetson Nano Orin has a CSI camera used in embedded systems. I then cam across this company that we will likely use for our camera called ardu cams :https://www.arducam.com/embedded-camera-module/nvidia-jetson-nano-camera-arducam/nvidia-jetson-nano-nx-officially-supported-sensors.html

Since then I have been running separate ai models on the jetson to get a feel for how it will perform under different memory usages since I do only have a128 GB micro sd installed which is also holding the OS. I might get a NVMe ssd where there are slots on the back side if memory becomes too much of an issue.
